Improving Transitions of Care With an Advanced Practice Nurse: A Pilot Study

Martha Tan-Fu Hsueh, DNP, RN-BC, and Kathleen Shannon Dorcy, RN, PhD

Gaps in complex oncology care coordination between inpatient and outpatient settings can result in treatment and monitoring delays and omissions, which can negatively affect patient outcomes. Gaps also exist for patients facing complex treatment modalities and Collaborations between multiple care teams working at geographically distant sites. A pilot advanced practice nurse care coordinator (APNCC) role to coordinate these complex care transitions and implement processes for safer and more efficient care has shown promise.

At a Glance

- Treatment and monitoring delays can negatively affect patient outcomes.
- The APNCC can minimize transition gaps, improve patient safety, and increase the quality of care delivery through effectiveness and efficiency.
- The APNCC pilot program reduced patient length of stay and infection rates.

Methods

The aim of the pilot study was to reduce length of stay (LOS), lower readmission rates, and decrease delays and misses in treatment during transitions from inpatient to outpatient care. The pilot was initiated with three resident physicians who care for about 50% of all inpatients with cancer in the hospital.

The advanced practice nurse care coordinator (APNCC) is a non-rotating member of the interprofessional team. When a patient is admitted to the hospital, the APNCC performs a comprehensive clinical, functional, social, and insurance assessment via chart audit to propose the best disposition plan. Throughout the stay, the APNCC coordinates and collaborates with other interprofessional staff to promote the most efficient transitions.

Patients with cancer receive the majority of their treatment in outpatient settings (Walter, 2013). At the University of Washington Medical Center (UWMC), where Seattle Cancer Care Alliance (SCCA) inpatients are housed, the authors identified gaps in care transitions from inpatient to outpatient settings through quality improvement initiatives. The specific gaps were clustered in categories from patient safety goals provided by the Joint Commission (2015).

Gaps during transitions in care play a key role in healthcare quality and safety. Improvements in complex oncology care must be made at the patient, provider, and system levels. The intersection of inpatient and outpatient settings is where care transitions are most crucial for ensuring both the quality and safety of care (Brez et al., 2009; Snow et al., 2009). Gaps during care transitions increase the health risks to patients as well as the liability risks for providers and care systems (Kelly, 2014). Medically complex patients with cancer have multiple treatment needs at discharge. Therefore, care transition gaps can pose serious risks, anxiety, and stress for these patients and their families if they are unable to access appropriate services and support. Case management can be effective in reducing care transition gaps but unable to show total cost efficiency (Stokes et al., 2015). The authors of the current article developed a pilot study with modifications from a case management model and other small quality improvement projects in UWMC and SCCA.
was initiated during the pilot to enable custom and detailed orders to improve patient safety. With the CPOE system, the home infusion order guide was transformed into a home infusion power order, which prompts providers during order entry to include specifics and ensures that line care protocol is followed uniformly. The APNCC also monitored process alignment and adjustment needs to propose transitional improvements whenever gaps arose. Timely communication among care team members is essential to orchestrate care coordination from admission to discharge (Blough & Walrath, 2007; Dingley, Daugherty, Derieg, & Persing, 2008). The inpatient team members include, but are not limited to, physicians, pharmacists, physical and occupational therapists, social workers, nurses, and medical specialty consultants. Additional oversight for safe patient transitions extends to the management of fluids and drug infusions, blood product needs, patient-specific transfusion precautions, supplemental nutrition, home oxygen, central line care, drains and wound care, medical equipment readiness, and transfers between hospitals. The APNCC uses daily team rounds to assess and realign transitional plans, addressing institutional quality measures and transitional gaps. Clerical support is provided by a part-time team assistant. APNCC—advanced practice nurse care coordinator; CLABSI—central line–associated bloodstream infection; JC—Joint Commission; LOS—length of stay; NPSG—National Patient Safety Goal

Note. Based on information from JC, 2015.
between transitional gaps addressed by the APNCC and the Joint Commission’s (2015) patient safety goals.

Findings

The APNCC who led the care transitions pilot program was effective in reducing inpatient LOS by well-planned dispositions starting at the time of admission and ensuring that necessary equipment, teaching, referrals, and follow-ups were in place when patients were medically ready for discharge. Readmission rates were not reduced but did remain the same. Although not part of the authors’ aim, central line–associated bloodstream infection (CLABSI) rates lowered after implementation of the central line care guide, following coordinated central line care teaching and flushing supplies referral together with scheduled weekly dressing changes after discharge.

The authors compared observed LOS against diagnosis-related group (DRG)-expected LOS per patient diagnosis. DRG-expected LOS was expressed as 1 in this comparison. Observed versus expected LOS ratio was reduced from 1.05 to 0.95 in the first year. The observed versus expected LOS ratio was further reduced to 0.86 in the second year (see Figure 1). These reductions in LOS ratio represent decreases in the actual number of inpatient days. Readmission rates did not diminish; a majority of readmissions were from neutropenic fevers related to chemotherapy-induced neutropenia). However, not having an increase in readmissions is considered a success. The hospital had seen an increase in readmissions in prior, unsuccessful, quality improvement projects. The CLABSI rate dropped in the first year, from eight cases in 2013 to three and two cases in 2014 and 2015, respectively.

Scheduled follow-up appointments, completed referrals, and written instructions at discharge all helped to lessen confusion and anxiety for both patients and families, clarified their expectations, and increased satisfaction. A survey on patient and family satisfaction with discharge information in the oncology units was reported at 94% compared to the institutional goal of 84%. Patient satisfaction with care transitions was 60% compared to the institutional goal of 53%.

The LOS reduction had financial savings implications for the institution and afforded patients more time at home with families. Oncologists reported feeling more supported in managing transitions one year after the integration of the APNCC role.

The oncology APNCC pilot project grew out of other APNCC pilots in medical, surgical, and neurologic units at UWMC. Based on the success of the current pilot program, an APNCC role has been replicated in cardiology. The APNCC connects and updates the interprofessional care team so that care progression and changing goals are monitored and communicated for smoother transitions for patients and families.

FIGURE 1. LOS of Inpatients With Cancer (N = 359)
Discussion

The average patient census managed by the APNCC is about 25–30 patients per day. Although the APNCC works across the institutional services spectrum to arrange the safe discharge transitions, the clinical team caring for the patient is still responsible for a safe discharge. The APNCC brings the comprehensive plan together through his or her leadership and oversight.

Specialty referrals and the provision of discharge medications can be a significant problem during transitions based on patients’ insurance coverage and eligibility, particularly for new medications and new diagnoses. Working closely with social workers, pharmacists, and ordering physicians, the APNCC ensures medications are accessible and available, and appropriate referrals are made by the time of discharge.

Limitations

Challenges existed related to the unwillingness of some team members to collaborate, and a sense by others of insufficient time and resources to meet the reduced LOS targets. Some patients were uneasy about being discharged earlier than expected, and their anxiety had to be addressed with sensitivity. In addition, some patients did not have adequate resources for optimal dispositions. Increasing resources in the areas of housing, home care, and support for caregivers is the next goal toward improving cancer care transitions.

Conclusion

The APNCC model was effective by initiating disposition planning at the time of hospital admission to prepare patients for discharge to the outpatient setting. The APNCC is the leader in assessing and coordinating care transitions while patients progress through their inpatient stay. The APNCC monitors the anticipated discharge needs of the patient in the context of payer requirements and coverage to ensure safe discharge. To date, barriers to further reductions in LOS relate to inadequate services provided through payer home or skilled nursing coverage and a lack of housing coverage for patients seeking care outside of their home geographic area. Payer coverage for telemedicine or telenursing monitoring should be considered to ensure symptom management to reduce readmissions and improve patient satisfaction. Payer coverage for housing and caregiver support may further reduce LOS because patients with neutropenia can have better outcomes at home than in skilled nursing facilities (Juthani-Mehta & Quagliarello, 2010). Finally, the APNCC model warrants additional testing in other complex patient populations.

Joint Commission (2015) guidelines provided an excellent benchmark to improve healthcare efficiency, reduce risks, sustain or improve healthcare outcomes, and improve patient and provider satisfaction. The current pilot project demonstrated the importance of the APNCC having a strong understanding of national and institutional quality standards. Identifying opportunities to improve patient care transitions and develop interventions using evidence-based outcome measures can guide progress in improving care.

Knowledge to improve healthcare quality should be built into all undergraduate and graduate nursing curriculums, particularly within graduate programs. To achieve ongoing quality improvement, all staff will need continued education on patient safety and quality goals. Nurses play an essential role in the improvement process.

The authors gratefully acknowledge University of Washington Medical Center Social Work and Care Coordination leadership and the clinical teams and patients who participated in this work.
